Variance Analysis Website- report.pdf

File Size

1.5 MB

7 Pages

1,270 Words

7,331 Characters

0% detected as AI

The percentage indicates the combined amount of likely AI-generated text as well as likely AI-generated text that was also likely AI-paraphrased.

Caution: Review required.

It is essential to understand the limitations of AI detection before making decisions about a student's work. We encourage you to learn more about Turnitin's AI detection capabilities before using the tool.

Detection Groups

1 AI-generated only 0%

Likely AI-generated text from a large-language model.

2 AI-generated text that was AI-paraphrased 0%

Likely AI-generated text that was likely revised using an AI-paraphrase tool or word spinner.

Disclaimer

Our AI writing assessment is designed to help educators identify text that might be prepared by a generative AI tool. Our AI writing assessment may not always be accurate (it may misidentify writing that is likely AI generated as AI generated and AI paraphrased or likely AI generated and AI paraphrased writing as only AI generated) so it should not be used as the sole basis for adverse actions against a student. It takes further scrutiny and human judgment in conjunction with an organization's application of its specific academic policies to determine whether any academic misconduct has occurred.

Frequently Asked Questions

How should I interpret Turnitin's AI writing percentage and false positives?

The percentage shown in the AI writing report is the amount of qualifying text within the submission that Turnitin's AI writing detection model determines was either likely AI-generated text from a large-language model or likely AI-generated text that was likely revised using an AI-paraphrase tool or word spinner.

False positives (incorrectly flagging human-written text as AI-generated) are a possibility in AI models.

AI detection scores under 20%, which we do not surface in new reports, have a higher likelihood of false positives. To reduce the likelihood of misinterpretation, no score or highlights are attributed and are indicated with an asterisk in the report (*%).

The AI writing percentage should not be the sole basis to determine whether misconduct has occurred. The reviewer/instructor should use the percentage as a means to start a formative conversation with their student and/or use it to examine the submitted assignment in accordance with their school's policies.

What does 'qualifying text' mean?

Our model only processes qualifying text in the form of long-form writing. Long-form writing means individual sentences contained in paragraphs that make up a longer piece of written work, such as an essay, a dissertation, or an article, etc. Qualifying text that has been determined to be likely AI-generated will be highlighted in cyan in the submission, and likely AI-generated and then likely AI-paraphrased will be highlighted purple.

Non-qualifying text, such as bullet points, annotated bibliographies, etc., will not be processed and can create disparity between the submission highlights and the percentage shown.

PRINCIPLES OF ACCOUNTING (II) REPORT:

Variance Analysis Website

By:

Ishaa Bhalekar (L004) Arpita Das (L005) Saanvi Kanodia (L014) Nidhi Shah (L025) Pavarna Bhatt (L037)

1. Introduction to Variance Analysis:

Variance analysis is a key tool used in management accounting to identify the discrepancies between actual and anticipated (or planned) financial performance. These variations can occur in a company's overhead, labour, and material costs, among other areas.

Variance analysis will improve performance management and reduce costs for businesses by providing insight to plan deviations in terms of which variables influence them. It is a widely used process for operation management and enhancing efficiency in budgeting, cost accounting, decision-making. Analysis of these differences helps companies assess how well they are doing compared to their standards or budget.

Favorable outcomes (F): This happens when actual performance is higher than budgeted or projected. For example, when the real expenses for input factors are less than those budgeted or projected or when income is better than budgeted or projected, this indicates that resources are utilised efficiently or more performance than what was budgeted or expected.

Adverse outcomes (A): these are results achieved in a situation where performance fails to achieve expectations. For instance, in the eventuality where revenues are less than the budgeted targets or the actual costs are higher than the budgeted estimates, it indicates that there are unfavorable circumstances or ineffective management. Negative deviations require an exploration of the causes so that appropriate remedies could be instituted.

Businesses use standard costs as a benchmark for evaluating their performance because they are predicted or estimated costs. They represent the estimated cost of manufacturing a good or service under typical circumstances. For direct materials, direct labour, and overheads, standard costs are set. Numerous factors, including past data, current market conditions, and projections for the future, influence these expenses.

By creating an application that can quickly calculate the variances of materials and labourers based on the user's inputs we can help managers create quick reports or error areas and take simple corrective measures.

2. Types of Variances and Their Importance:

2.1. Material Variances:

- <u>Price Variance</u>: Difference between the actual price and the standard price of materials $MPV = (AP - SP) \times AQ$
- <u>Cost Variance</u>: Measures the difference between actual and expected material costs $MCV = (SQ \times SC) - (AQ \times AC)$
- <u>Mix Variance</u>: Measures the difference in material mix used compared to the standard mix.

$$MMV = (R.St. Qty - AQ) \times SP$$

<u>Usage Variance</u>: Measures the difference between Standard Quantity that estimated for and the Actual Quantity of materials used, valued at Standard Cost per Unit

$$MUV = SP / Q \times (SQ - AQ)$$

Yield Variance: Measures the difference between Standard Output (based on Actual Materials) and Actual Output valued at Standard Cost per Unit.

$$MYV = (AO - SO) \times SP / Q$$

2.2. Labour Variances:

Rate Variance: Labour Rate Variance (LRV) is the variation between the actual and expected or standard cost of labour.

$$LRV = (SR - AR) x AH$$

Cost Variance: Labour Cost Variance is the difference between the standard cost of labour for the actual output and the actual cost of labour for the production.

$$LCV = (SH \times SR) - (AH \times AR)$$

Idle Time Variance: Idle time is paid time that an employee machine is unproductive due to factors that can either be controllable or uncontrollable by management.

$$LITV = Idle Time x SH / Q$$

Mix Variance: An analysis used in cost accounting to measure the impact of changes in the composition of a labour force on the overall labour cost.

$$LMV = (RStd. Hours - AH) x SR$$

Efficiency Variance: Expresses the difference between the estimated hours and the actual number of hours worked, valued at the standard rate per hour.

$$LEV = SR x (SH - AH)$$

<u>Labour Yield Variance</u>: Pertains to the variance arising from differences in labour productivity or efficiency compared to the standard labour input.

LYV = (SH - R.Std.H) * Standard Rate / (Standard Yield – Actual Yield) * Standard Rate

3. Variance Analysis Tool:

This application simplifies the calculation of different variances. Rather than doing these calculations manually, the application requires an entry of the relevant data, after which the calculated variances are generated. This tool, therefore, helps companies analyze their production, identifies areas where inefficiency has occurred, and points out areas that require improvement.

3.1. Overview of the App's Functionality:

- Input fields: the application contains input fields where actual and standard values for material and labor data are to be entered.
- Calculation Engine: uses similar formulas mentioned above, and accordingly, it
 processes the data. The application calculates results related to price, usage, rate, and
 efficiency variances.
- output: the application gives variance calculations. That is all users need to grasp cost deviations and overall performances.

Understanding Standard Costing and Variance Analysis

Variance analysis helps businesses measure the difference between expected and actual performance

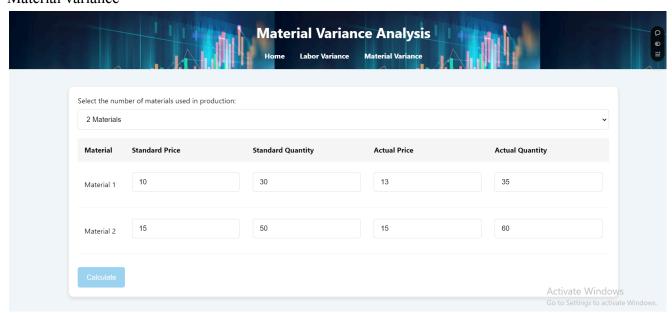

Some Important of Variances Material Price Variance Material Quantity Variance Labor Rate Variance Labor Efficiency Variance Overhead Variance Formula: (Actual Price -Formula: (Actual Quantity -Formula: (Actual Rate Formula: (Actual Hours -Formula: Actual Overhead Applied Overhead Standard Price) x Actual Standard Quantity) x Standard Standard Rate) x Actual Hours Standard Hours) x Standard Quantity Price Rate Description: Measures the Description: Reflects the Description: Measures the Description: Indicates the Description: Shows the difference between the actual difference between the actual difference between the actual labor rate paid and the standard difference in cost between what difference between the actual overhead costs incurred and the was paid for materials and what quantity of materials used and labor rate set by the company. hours worked and the standard overhead applied based on should have been paid the standard quantity expected hours expected for the actual standard rates. according to the standard. to be used. output.

Labour Variances

Material variance

3.3. Code Explanation:

The variance analysis tool enables managers to evaluate discrepancies in their costs, including materials and labour, by computing various types of variances. This webpage allows users to calculate material variances by inputting standard and actual values for up to four materials used in production. It provides a user-friendly interface for variance calculations, with a download report option for detailed results.

The key sections are:

i. Home page section: Contains an overview of what standard costing variances are, and some of the common and important variances used in the industry. It also contains a navigation bar at the top with hyper-links to the page that actually calculates material and labour variances.

<u>ii. Labour Variance</u>: This page will calculate all labour variances based on user given inputs. It Allows users to select the number of materials used in a product and based on their selection, giving them the option to enter standard and actual prices and quantities.

The application uses a code stack of HTML, CSS and JAVA script. Styling with CSS: There was an extensive use of CSS (Cascading Style Sheets) was made to improve the visual design and layout of the tool.

Javascript usage:

i. Input forms: users may enter actual and standard values (e. g., standard price, actual quantity) in the designated form fields.

ii. Calculation logic: Upon submission of the form by the user, JavaScript functions compute various types of variances (including material price variance, material yield variance, and labor rate variance) using established formulas. The results are presented dynamically on the web page.

iii. Report Generation: After calculating the variances, the tool enables users to download the results in a text format using the downloadreport() function.

User Interaction:

i. Navigation: users can navigate between various sections, such as labor and material variance calculations, using the navigation bar.

ii. Form inputs: The interactive forms enable users to enter data pertaining to actual and standard values, subsequently generating output based on the variance formulas.

Conclusion:

Variance analysis is an insightful tool in managerial accounting that enables businesses to monitor and control costs, efficiency assessment, and overall improvement of the production process. It takes actual results and compares them with estimated standard costs and budgets to understand the reasons for favorable variances and unfavorable variance and take corrective measures. From the viewpoint of materials, labor, or overhead, variance analysis gives very important information for better decision-making and resource management. In the future we hope to be able to create a much more detailed report which can give users personalized advice on how to reduce the variances in their budget and actual results by using AI-integration.
